ORDERS OF GROWTH

$$T(n) = \Theta(f(n))$$

$$\iff T(n) = O(f(n)) \text{ and } T(n) = \Omega(f(n))$$

$$T(n) = O(f(n))$$
 if $\exists c, n_0 > 0$ such that for all $n > n_0, T(n) \leq cf(n)$
$$T(n) = \Omega(f(n))$$
 if $\exists c, n_0 > 0$ such that for all $n > n_0, T(n) \geq cf(n)$

properties

Let T(n) = O(f(n)) and S(n) = O(g(n))

- addition: T(n) + S(n) = O(f(n) + g(n))
- multiplication: T(n) * S(n) = O(f(n) * g(n))
- composition: $f_1 \circ f_2 = O(g_1 \circ g_2)$ only if both increasing
- if/else statements: $\cos t = \max(c1,c2) \le c1+c2$
- max: $\max(f(n), g(n)) \le f(n) + g(n)$
- $\Theta(f(n))$ time complexity $\Rightarrow O(f(n))$ space complexity
- space complexity: once we exit the function, release all memory that was used

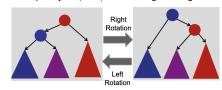

QUICKSORT

- stable quicksort: $O(\log n)$ space (due to recursion stack)
- worst case $O(n^2)$: pivot first/last/middle element
- worst case $O(n \log n)$: median/random element/fraction
- · choose at random: runtime is a random variable

TREES

AVL Trees

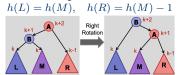

- height-balanced (maintained with rotations)
- \iff |v.left.height v.right.height| ≤ 1
- each node is augmented with its height v.height = h(v)
- space complexity: O(LN) for N strings of length L

insertion - max 2 rotations; deletion - recurse all the way up;

rebalancing

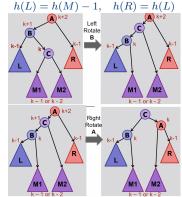

[case 1] B is balanced: right-rotate

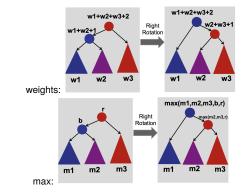

[case 2] B is left-heavy: right-rotate

$$h(L) = h(M) + 1, \quad h(R) = h(M)$$
Rotation
Rotat

[case 3] B is right-heavy: left-rotate(v.left), right-rotate(v)

updating nodes after rotation

binary search trees (BST)

- balanced: $O(h) = O(\log n)$ (depends on insertion order)
- for a full-binary tree of size $n, \exists k \in \mathbb{Z}^+$ s.t. $n = 2^k 1$
- height, h(v) = max(h(v.left), h(v.right))
- leaf nodes: h(v) = 0
- search, insert O(h)
- delete O(h)
- no children remove the node
- · 1 child remove the node, connect parent to child
- 2 children delete successor; replace node w successor
- searchMin/Max O(h) recurse into left/right subtree
- successor O(h)
- if node has a right subtree: searchMin(v.right)
- else: traverse upwards and return the first parent that contains the key in its left subtree
- · merkle trees
- binary tree nodes augmented with a hash of their children
- same root value = identical tree

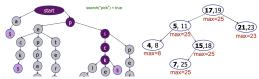

Trie

- search, insert O(L) (for string of length L)
- space: O(size of text · overhead)

interval trees

- search(key) $\Rightarrow O(\log n)$
- · if value is in root interval, return
- if value > max(left subtree), recurse right

- else recurse left (go left only when can't go right)
- all-overlaps $\Rightarrow O(k \log n)$ for k overlapping intervals

orthogonal range searching

- binary tree; leaves store points, internal nodes store max value in left subtree
- buildTree(points[]) $\Rightarrow O(n \log n)$ (space is O(n))
- query(low, hight) $\Rightarrow O(k + \log n)$ for k points
- v=findSplit() $\Rightarrow O(\log n)$ find node b/w low & high
- leftTraversal(v) $\Rightarrow O(k)$ either output all the right subtree and recurse left, or recurse right
- rightTraversal(v) symmetric
- insert(key), insert(key) $\Rightarrow O(\log n)$
- 2D_query() $\Rightarrow O(\log^2 n + k)$ (space is $O(n \log n)$)
- build x-tree from x-coordinates; for each node, build a y-tree from y-coordinates of subtree
- 2D_buildTree(points[]) $\Rightarrow O(n \log n)$

kd-Tree

- stores geometric data (points in an (x, y) plane)
- ullet alternates splitting (partitioning) via x and y coordinates

(a, b)-trees

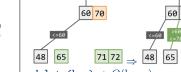

e.g. a (2, 4)-tree storing 18 keys

- rules
- 1. (a, b)-child policy where $2 \le a \le (b+1)/2$

	# keys		# children	
node type	min	max	min	max
root	1	b-1	2	b
internal	a-1	b-1	a	b
leaf	a-1	b-1	0	0

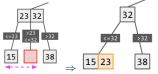

- 2. an internal node has 1 more child than its number of keys
- 3. all leaf nodes must be at the **same depth** from the root
- terminology (for a node z)
- ullet key range range of keys covered in subtree rooted at z
- keylist list of keys within z; treelist list of z's children
- max height = $O(\log_a n) + 1$; min height = $O(\log_b n)$
- search(key) $\Rightarrow O(\log n)$
- = $O(\log_2 b \cdot \log_a n)$ for binary search at each node
- insert(key) $\Rightarrow O(\log n)$
- split() a node with too many children
- 1. use median to split the keylist into 2 halves
- 2. move median key to parent; re-connect remaining nodes

- delete(key) $\Rightarrow O(\log n)$
- if the node becomes empty, merge(y, z) join it with its left sibling & replace it with their parent

3. (if the parent is now unbalanced, recurse upwards; if the

root is reached, median key becomes the new root)

if the combined nodes exceed max size: share(y, z) = merge(y, z) then split()

B-Tree (aka (B, 2B)-trees)

 possible augmentation: use a linkedList to connect between each level

HASH TABLES

Let the m be the table size; let n be the number of items; let cost(h) be the cost of the hash function

- $load(hash table), \alpha = \frac{n}{m}$
- = average & expected number of items per bucket
- designing hashing techniques
- division method: $h(k) = k \mod m$ (m is prime)
- don't choose $m=2^x$
- if k and m have common divisor d, only $\frac{1}{d}$ of the table will be used
- · multiplication method -

 $h(k) = (Ak) \bmod 2^w \gg (w-r)$ for odd constant A and $m = 2^r$ and w =size of a key in bits

- simple uniform hashing assumption
- (1) every key has an equal probability of being mapped to every bucket; (2) keys are mapped independently
- uniform hashing assumption
- every key is equally likely to be mapped to every permutation, independent of every other key.
- · NOT fulfilled by linear probing

· properties of a good hash function

- 1. able to enumerate all possible buckets $h: U \to \{1..m\}$
 - for every bucket j, $\exists i$ such that h(key, i) = j
- 2. simple uniform hashing assumption

hashCode

rules for the hashCode() method

- 1. always returns the same value, if object hasn't changed
- 2. if two objects are equal, they return the same hashCode

rules for the equals method

- reflexive, symmetric, transitive for $xRy \iff x.equals(y)$
- consistent always returns the same answer
 null is null x.equals(null) => false

chaining

- insert(key, value) $O(1 + cost(h)) \Rightarrow O(1)$
- for *n* items: expected maximum cost = $O(\log n)$
 - = $\Theta(\frac{\log n}{\log(\log(n))})$

- search(key)
- worst case: $O(n + cost(h)) \Rightarrow O(n)$
- expected case: $O(\frac{n}{m} + cost(h)) \Rightarrow O(1)$ total space: O(m+n)

open addressing - linear probing

- redefined hash function: $h(k, i) = h(k, 1) + i \mod m$
- delete(key): use a tombstone value DON'T set to null
- **performance** (assume $\alpha < 1$ and uniform hashing)
- if the table is $\frac{1}{4}$ full, there will be clusters of size $\Theta(\log n)$
- expected cost of an operation, $E[\#probes] \leq \frac{1}{1-\alpha}$

double hashing

for 2 functions f, q, define $h(k, i) = f(k) + i \cdot g(k) \bmod m$

- if q(k) is relatively prime to m, then h(k, i) hits all buckets
- e.g. for $q(k) = n^k$, n and m should be coprime.

table size

assume chaining & simple uniform hashing growing the table: $O(m_1 + m_2 + n)$

table growth	resize	insert n items
increment by 1	O(n)	$O(n^2)$
double	O(n)	O(n), average $O(1)$
square	$O(n^2)$	O(n)

SET ADT

 ✓ speed ✓ space ✓ no false negatives × no orderina

fingerprint hash table

- ullet only stores m bits does not store the key in a table
- P(no false positives) with SUHA $=(1-\frac{1}{m})^n \approx (\frac{1}{e}^{n/m})$ i.e. probability of nothing else in the given (same) bucket for P(no false positives) < p, need $\frac{n}{m} \leq \log(\frac{1}{1-p})$

bloom filter

sort

bubble

selection

insertion

merge

auick

heap

- 2 hash functions requires 2 collisions for a false positive
- for k hash functions (assume independent slots):
- $\begin{array}{l} \bullet \ P(\text{a given bit is } \mathbf{0}) = (1-\frac{1}{m})^{kn} \approx (\frac{1}{e})^{kn/m} \\ \bullet \ P(\text{false positive}) = (1-(\frac{1}{e})^{kn/m})^k \end{array}$
- $P(\text{no false positives}) < p, \text{ need } \frac{n}{m} \leq \frac{1}{k} \log(\frac{1}{1 n^{1/k}})$
- optimal $k = \frac{m}{n} \ln 2$ \Rightarrow error probability $= 2^{-k}$
- delete operation: store counter instead of 1 bit
- insert, delete, query $\Rightarrow O(k)$
- intersection (bitwise AND), union (OR) $\Rightarrow O(m)$
- gives the same false positives as both

PROBABILITY THEORY

X

for random variables: expectation is always = probability

• linearity of expectation: E[A + B] = E[A] + E[B]

UNIFORMLY RANDOM PERMUTATION

- for an array of n items, every of the n! possible permutations are producible with probability of exactly $\frac{1}{2}$
- the number of outcomes should distribute over each permutation uniformly. (i.e. $\frac{\text{\# of outcomes}}{\text{\# of permutations}} \in \mathbb{N}$)
- probability of an item remaining in its initial position $=\frac{1}{n}$
- KnuthShuffle $\Rightarrow O(n)$ for (i = n-1..0) { swap(i, rand(0, i)) }

AMORTIZED ANALYSIS

an operation has **amortized cost** T(n) if for every integer k, the cost of k operations is $\leq kT(n)$.

- binary counter ADT: increment $\Rightarrow O(1)$
- hash table resizing: O(k) for k insertions $\Rightarrow O(1)$
- search operation: expected O(1) (not amortized)

GRAPHS

• graph is **dense** if $|E| = \theta(V^2)$

	adj	space	(cycle)	(clique)	use for
	list	O(V+E)	O(V)	$O(V^2)$	sparse
Ī	matrix	$O(V^2)$	$O(V^2)$	$O(V^2)$	dense

searching

- breadth-first search $\Rightarrow O(V + E)$ queue
- O(V) every vertex is added exactly once to a frontier
- O(E) every neighbourList is enumerated once
- parent edges form a tree & shortest path from S
- depth-first search $\Rightarrow O(V+E)$ stack
- O(V) DFSvisit is called exactly once per node
- O(E) DFSvisit enumerates each neighbour
- with adjacency matrix: O(V) per node \Rightarrow total $O(V^2)$

shortest paths

- Bellman-Ford $\Rightarrow O(VE)$
- \bullet |V| iterations of relaxing every edge terminate when an entire sequence of |E| operations have no effect
- Dijkstra $\Rightarrow O((V+E)\log V) = O(E\log V)$
- · no negative weight edges!
- using a PQ to track the min-estimate node, relax its outgoing edges and add incoming nodes to the PQ
- |V| times of insert/deleteMin ($\log V$ each)
- |E| times of relax/decreaseKey ($\log V$ each)
- with fibonacci heap $\Rightarrow O(E + V \log V)$
- for DAG $\Rightarrow O(E)$ (topo-sort and relax in this order)
- · longest path: negate the edges/modify relax function
- for Trees $\Rightarrow O(V)$ (relax each edge in BFS/DFS order)

sorting invariants

invariant (after k iterations)

largest k elements are sorted

first k: slots are sorted

given subarray is sorted

add nodes without incoming edges to the topological order

- remove min-degree node from PQ $\Rightarrow O(V \log V)$
- decreaseKev (in-degree) of its children $\Rightarrow O(E \log V)$
- Kahn's algorithm (tutorial vers.) $\Rightarrow O(E+V)$
- add nodes with in-degree=0 to a queue; decrement the in-degree of its adjacent nodes. dequeue & repeat

spanning trees

- anv 2 subtrees of the MSTs are also MSTs
- for every cycle, the maximum weight edge is NOT in the MST
- for every partition of the nodes, the minimum weight edge across the cut is in the MST
- for every vertex, the minimum outgoing edge is in the MST.
- · Steiner Tree: (NP-hard) MST containing a given set of nodes
- 1. calculate the shortest path between any 2 vertices
- 2. construct new graph on required nodes
- 3. MST the new graph and map edges back to original

MST algorithms

- Prim's $O(E \log V)$
- · add the minimum edge across the cut to MST
- PQ to store nodes (priority: lowest incoming edge weight)
- each vertex: one insert/extractMin $\Rightarrow O(V \log V)$
- each edge: one decreaseKey $\Rightarrow O(E \log V)$
- Kruskal's $O(E \log V)$
- · sort edges by weight, add edges if unconnected
- sorting $\Rightarrow O(E \log E) = O(E \log V)$
- each edge: find/union $\Rightarrow O(\log V)$ using union-find DS
- Boruvka's $O(E \log V)$
- each node: store a component $d \Rightarrow O(V)$
- one Boruvka step: for each cc. add minimum weight outgoing edge to merge cc's $\Rightarrow O(V + E)$ dfs/bfs
- at most $O(\log V)$ Boruvka steps • update componentlds $\Rightarrow O(V)$
- directed MST with one root $\Rightarrow O(E)$
- · for every node, add minimum weight incoming edge

HEAPS

- 1. **heap ordering** priority[parent] ≥ priority[child]
- 2. complete binary tree every level (except last level) is full; all nodes as far left as possible
- operations: all $O(\max height) = O(\lfloor \log n \rfloor)$
- insert: insert as leaf, bubble up to fix ordering
- increase/decreaseKey: bubble up/down leftwards
- delete: swap w bottomrightmost in subtree; bubble down
- extractMax: delete(root)
- heap as an array:

smallest k elements are sorted 2. **overlapping sub-problems** - can memoize

- left(x) = 2x + 1, right(x) = 2x + 2• parent(x) = $\lfloor \frac{x-1}{2} \rfloor$
- HeapSort: $\Rightarrow O(n \log n)$ always
- unsorted arr to heap: O(n) (bubble down, low to high)
- heap to sorted arr: $O(n \log n)$ (extractMax, swap to back)

DYNAMIC PROGRAMMING

- optimal sub-structure optimal solution can be constructed from optimal solutions to smaller sub-problems
- optimal substructure but no overlapping subproblems = divide-and-conquer
- partition is in the right position

UNION-FIND

- quick-find int[] componentId, flat trees
 - O(1) find check if objects have the same componently
 - O(n) union enumerate all items in array to update id
 - quick-union int[] parent, deeper trees
 - O(n) find check for same root (common parent) • O(n) union - add as a subtree of the root
 - weighted union int[] parent, int[] size
 - $O(\log n)$ find check for same root (common parent)
 - $O(\log n)$ union add as a smaller tree as subtree of root
 - path compression set parent of each traversed node to the root - $O(\log n)$ find, $O(\log n)$ union
 - · a binomial tree remains a binomial tree
- weighted union + path compression for m union/find operations on n objects: $O(n + m\alpha(m, n))$
- $O(\alpha(m,n))$ find, $O(\alpha(m,n))$ union
